1 Fully Distributive Evaluation Protocol

The key is structured as a vector in \mathbb{Z}_2

The protocol is divided into three phases:

1.1 Phase 1:

Each server S_i holds replicated additive shares of key $k_i \in \mathbb{Z}_n^2$ and $x_i \in \mathbb{Z}_n^2$ and computes h , which is the multiplication of key and input over \mathbb{Z}_2 . This computation is performed locally.

1.2 Phase 2:

1. Each server, at this point have locally computed their shares, which was the multiplication of two vectors.
2. Server 1 randomly chooses a value $c \in \mathbb{Z}_3^m$ and each bit of value is converted to it's 2-bit representation to form c_0 and c_1 respectively.
3. Meanwhile, Server 1

1.3 Phase 3:
